1. Let $I=\int_{0}^{3} e^{-x^{4}} d x$.
(a) Check that Theorem 1 applies, and use this to find an $n$ so that $R_{n}$ approximates $I$ within $10^{-6}$ of its actual value.
(b) Now use Theorem 2 to find an $n$ so that $R_{n}$ approximates $I$ within $10^{-6}$ of its actual value.
(c) Use Theorem 3 to find an $n$ so that $M_{n}$ approximates $I$ within $10^{-6}$ of its actual value.

Calculate $M_{n}$ for this value of $n$.
2. Let $I=\int_{0}^{2} \sqrt{4-x^{2}} d x$.
(a) Check that Theorem 1 applies, and use this to find an $n$ so that $L_{n}$ approximates $I$ within 0.001 of its actual value.
(b) Now try to use use Theorem 2 to find an $n$ so that $L_{n}$ approximates $I$ within 0.001 of its actual value.
(Look very closely near $x=2$ )
What's happening? Why?
(c) What is the exact value of $I$ ?
