1. Let 
$$I = \int_0^3 e^{-x^4} dx$$
.

- (a) Check that Theorem 1 applies, and use this to find an n so that  $R_n$  approximates I within  $10^{-6}$  of its actual value.
- (b) Now use Theorem 2 to find an n so that  $R_n$  approximates I within  $10^{-6}$  of its actual value.
- (c) Use Theorem 3 to find an n so that  $M_n$  approximates I within  $10^{-6}$  of its actual value. Calculate  $M_n$  for this value of n.

2. Let 
$$I = \int_0^2 \sqrt{4 - x^2} \, dx$$
.

- (a) Check that Theorem 1 applies, and use this to find an n so that  $L_n$  approximates I within 0.001 of its actual value.
- (b) Now try to use use Theorem 2 to find an n so that  $L_n$  approximates I within 0.001 of its actual value. (Look very closely near x=2) What's happening? Why?
- (c) What is the exact value of I?
